Comprehensive Report: Quantum Integration for Biologics Drug Discovery

Target Audience: Management / Non-Technical Stakeholders
Date: March 17, 2026
Subject: Deploying the Origin PilotOS Quantum Simulation Module Locally

---

1. Executive Summary: What is this "Quantum" Module?

The module we are integrating is the **Origin PilotOS (本源司南)**. For a non-technical audience, think of this as a **"Virtual Quantum Brain"**.

In traditional drug discovery, our computers sometimes get "stuck" when trying to simulate complex proteins because there are too many variables. Quantum computing processes these variables all at once rather than one by one. By adding this module to our **Biologics Drug Discovery Platform**, we are preparing our infrastructure to solve molecular docking and protein folding problems that were previously impossible.

---

2. Security & Data Privacy (The "Manager's Answer")

A primary concern is whether our proprietary molecular data is being sent to external servers.

The answer is No.

- **100% Local Execution**: The software is running entirely on our own laptop/server. It uses a technology called **Docker** to create a private "bubble" for the software to live in.
- **Air-Gapped Communication**: The "Platform" and the "Quantum Module" talk to each other inside the computer using a private channel (ZMQ). This channel is locked to our machine and cannot be accessed from the outside.
- **Data Sovereignty**: Our Biologics data remains within our firewall. No info is sent to OriginQC or any third-party servers.

---

3. How the Model Works (The "Digital Twin")

Since full-scale quantum computers are still massive and experimental, we are using a **Digital Twin Simulator**.

1. **Preparation**: Our Biologics platform identifies a moleule.

2. **Simulation**: Instead of using a real quantum chip, we use this "Digital Twin" on our server to *simulate* how a quantum chip would behave.
3. **Result**: We get the same high-quality data we would get from a real quantum computer, allowing us to refine our drug candidates today while others are still waiting for hardware access.

---

4. Integration & Deployment Guide

To connect our existing **Biologics Discovery Platform** to this new Quantum Module, we follow these three simple steps:

Step A: Deployment (One-Time Setup)

We run the provided "AutoDeploy" script which sets up the local database and the Docker environment. Once started, the "Quantum Dashboard" is available locally on our internal network.

Step B: The "Quantum Bridge" (Connecting Code)

We use a small piece of "Bridge Code" in our Biologics platform. This bridge sends the molecular data to the local "Quantum Brain" on Port 7000 and waits for the result.

Step C: Verification

We run a "Validation Test" to ensure the link is active. If the test passes, the Biologics platform can now call quantum sub-routines whenever it needs extra power.

---

5. Deployment Roadmap

Phase	Goal	Business Value
Stage 1 (Current)	Local Simulation	Data stays 100% private; developers can build quantum-ready drug discovery tools today.
Stage 2 (Short Term)	HPC Cluster Integration	Scale up our local simulation to handle massive protein structures using our company's high-performance servers.
Stage 3 (Future)	Real Hardware	Port our tested code to actual quantum hardware for final, world-leading speed breakthroughs.

---

6. Closing & Next Steps

By deploying this locally, we have secured a first-mover advantage in **Quantum Drug Discovery** without exposing any of our data. The system is live, tested, and ready for our engineers to begin plugging in our docking algorithms.

Recommendation: Approve the transition of Phase 1 (Simulation) into our daily R&D pipeline.

End of Report.
