Strategic Guidance: Quantum-AI PIN1 Platform

Based on the strategic vision and a comprehensive audit of the current codebase in `backend/app`, here is the technical assessment and execution strategy.

1. System Requirements & Infrastructure

To transition from the current MVP to a production-grade Quantum-AI platform, the following stack is required:

A. Compute Infrastructure (AI & Classical)

- **Training Cluster**: NVIDIA A100 or H100 GPU nodes (8x multi-pair) for training Diffusion and GNN models (Layer 5).
- **Inference/Docking**: CPU/GPU hybrid cluster. Classical docking (AutoDock Vina) is CPU-bound but massively parallelizable via **Kubernetes**.
- **Model Registry**: **MLFlow** or **Weights & Biases** for experiment tracking (currently missing).
- **Workflow Orchestration**: **Apache Airflow** or **Prefect** to manage the "collaboration workflow" (1 → 8).

B. Personal Workstation Recommendations (Local Development)

For designers and developers without existing GPU hardware, the following systems are recommended to support local model orchestration and quantum simulation:

Tier	Recommended Model	Key Specs	Price Range
Ultimate AI	**MacBook Pro 16" (M4 Max)**	128GB Unified Memory, 40-Core GPU	~$4,500 - $5,500
CUDA Power	**ASUS ROG Zephyrus G16**	RTX 5090 (16GB), 64GB RAM, OLED	~$3,500 - $4,200
Professional	**Dell Precision 7680**	RTX 2000 Ada, 32GB RAM, i9-13th Gen	~$2,400 - $3,000
Entry AI	**MacBook Air 15" (M3)**	24GB RAM, 1TB SSD (Portable)	~$1,800 - $2,200

> **[!NOTE]** High unified memory (Apple) or high VRAM (NVIDIA) is critical for running large structural models (AlphaFold) or quantum simulators locally.

C. Quantum Infrastructure

- **Frameworks**: Qiskit (Python-based) for circuit design.
- **Runtime**: Hybrid Quantum-Classical architecture using **Qiskit Runtime** for low-latency iterations.
- **Hardware**: Access to **IBM Quantum (Eagle/Osprey)** or **Azure Quantum**.

2. Code Readiness Audit

The current implementation is an **Advanced MVP (Level 2-3)**.

Layer	Status	Code Reference	Gap Analysis
Layer 4: Structural	✅ Ready	`alphafold_service.py`	Basic metadata fetching; needs AlphaFold-Multimer integration.
Layer 5: GenAI	⚠️ Alpha	`optimization.py`	Uses GA (Genetic Algorithm). Needs Diffusion/Transformer upgrade.
Layer 6: Screening	✅ Ready	`screening.py`	Functional XGBoost screening. Needs physical docking post-inference.
Layer 7: Quantum	❌ **Missing**	N/A	No Qiskit or VQE implementation found.
Layer 8: ADMET	⚠️ Alpha	`admet.py`	Heuristic-based. Needs ensemble deep learning models.

> **[!IMPORTANT] Can the current code run the platform?** Partially. It can perform early-stage hit discovery and lead optimization, but it **cannot** perform quantum validation or systems biology simulation without new module development.

3. Quantum Impact Analysis

A. Speed & Accuracy (VQE vs Classical)

Classical docking uses "Scoring Functions" (Energy Grids). Quantum Molecular Simulation focuses on Electronic Structure. - **Classical (AutoDock Vina)**: ~1-5 seconds per pose. High false-positives. - **Quantum (VQE Refinement)**: ~10-30 minutes per molecule (on simulators) or few seconds on hardware + queue time. - **The Speedup**: Quantum doesn't make discovery "faster" in seconds; it makes it "faster" in **success rate**. High-precision binding energy prevents late-stage clinical failures.

B. Approximate Cost (Model-Wise)

Estimates based on IBM Quantum Premium Access.

Task	Quantum Model	Estimated Cost	Hardware Need
Binding Refinement	VQE (Variational Quantum Eigensolver)	~$150 - $400 / molecule	20+ Error-Corrected Qubits
Vibrational Analysis	QPE (Quantum Phase Est.)	~$1k+ / molecule	High-fidelity depth (Future)
SAR Optimization	Quantum GNN	~$50 / optimization step	Noisy Intermediate-Scale (NISQ)

4. Infrastructure Costing & Financial Projections

Estimated figures for 2026 Cloud-Native discovery workloads.

A. Monthly Infrastructure OpEx (Classical/AI)

Item	Unit	Estimated Cost	Total (Moderate Usage)
GPU Compute (8x H100)	per Hour	$25 - $35	~$18k - $25k / mo
Worker Nodes (CPU)	per Cluster	$2.5k / mo	$2.5k / mo
K8s Control Plane	per Month	$75	$75
Storage (Bio-Datasets)	per TB	$25 (Object)	$250 (10TB)
Total Baseline			**~$21k - $28k / mo**

> **[!TIP]** Use **Spot Instances** for large virtual screening batches to reduce GPU costs by up to 60-70%.

B. Quantum Validation Costs (Per Discovery Milestone)

Milestone: High-precision refinement of Top 20 Candidates.

Service	Model	Cost per Run	Total Project Cost
IBM Quantum	Flex Plan (VQE)	$72 / min	~$14.4k (200 mins)
Azure Quantum	IonQ Tokens	$97.50 min/exec	~$2k (Per Batch)

5. Summary: High-Level Investment Required

- **MVP Phase (Current)**: ~$500 - $2k / mo (Low-tier GPUs + Free Tier K8s).
- **Scale Phase (Active Discovery)**: ~$30k - $50k / mo (Full GPU Cluster + Quantum Validation).
- **Enterprise Phase**: $500k+ / Annual reserved capacity with direct Quantum partnership.

6. Strategic Implementation Roadmap

1. **Initialize Layer 7**: Create `backend/app/services/quantum_service.py` using Qiskit.
2. **Hybrid Workflow**: Modify `optimization.py` to call `quantum_service.refine_pose()` for the top 10 candidates found by the Genetic Algorithm.
3. **Deploy on Cloud**: Move the local FastAPI server to a Dockerized Kubernetes environment to support asynchronous compute-heavy tasks.
